### 1. INTRODUCTION

Mushrooms are the fruiting bodies of some members of a lower group of shops called fungi. The Mushrooms appearing after rains in colorful shapes, sizes, and colors have fascinated individuals since yore and were bound to draw the attention of humans indeed after they were living as nimrods and gatherers. While a man started husbandry 10,000 times ago, the civilization of mushrooms may be a comparatively new miracle and has picked up across the globe only within the last century has witnessed newer inventions and operations. The Chinese were reportedly the first to instinctively cultivate tropical and sub-tropical mushrooms thousands of times back but marketable products started in Europe with button mushrooms in grottoes during the 16th and 17th centuries. The mushroom civilization also made its due to the U.S.

- The term mushroom means in general a fungus but commonly it is the fruiting body of some fungi which produce and disseminate spores.
- Like all other fungi, they lack Chlorophyll and thus cannot produce their own food. They grow saprophytically or sometimes symbiotically upon other dead and living plants respectively to obtain organic matter as food. Reproduces through spores and play crucial role in ecosystems as decomposers.
- Contains many vitamins and minerals but has amount of sugar and fat.
- Can be grown in artificially created and controlled environment.
- It is substitute of meat and egg and is easily digestible.
- Some mushrooms are sources of food for animals and humans but some mushrooms are toxic.

#### Objective of mushroom cultivation

The objective of mushroom cultivation is to grow and produce mushrooms under controlled conditions for various purposes. Here are some common objectives of mushroom cultivation:

- Food production: One of the primary objectives of mushroom cultivation is to produce edible mushrooms for human consumption. Mushrooms are a nutritious food source that contains essential vitamins, minerals, and dietary fiber. They are also a good source of protein and can be a meat substitute for vegetarians and vegans.
- Medicinal uses: Certain mushroom species have medicinal properties and are used in traditional medicine and modern pharmaceuticals. Mushroom cultivation aims to produce these medicinal mushrooms to extract bioactive

compounds that have potential therapeutic applications. Examples include mushrooms like Reishi, Shiitake, and Lion's Mane, which are known for their immune-boosting, antioxidant, and cognitive enhancing properties.

- Industrial applications: Mushrooms have several industrial uses. For example, some species of mushrooms are cultivated for their enzymes, which can be used in various industrial processes such as food processing, textile manufacturing, and biofuel production. Additionally, certain mushrooms can be used in the production of biodegradable packaging materials and as biofilters for water and air purification.
- Research and education: Mushroom cultivation serves as a valuable platform for research and education. Scientists and researchers study various aspects of mushroom cultivation, including genetics, breeding, cultivation techniques, and mushroom physiology. Cultivation provides an opportunity to understand the biology and ecology of mushrooms better. Additionally, it offers hands-on learning experiences for students and enthusiasts interested in mycology and agricultural sciences.
- Income generation: Mushroom cultivation can be a profitable agricultural venture. With proper knowledge and techniques, mushrooms can be grown on a small scale or in large commercial operations, providing a source of income for farmers and entrepreneurs. Mushrooms have a relatively short growing cycle compared to many other crops, allowing for multiple harvests in a year and a potential for high yields.
- Environmental benefits: Mushroom cultivation has several environmental advantages. Mushrooms can be grown using agricultural waste products such as straw, sawdust, or wood chips, reducing the need for land and water resources.

Additionally, some mushroom species can break down and decompose organic matter, contributing to nutrient cycling and soil health. Mushroom cultivation can be an eco-friendly farming practice with minimal environmental impact. Overall, the objective of mushroom cultivation can vary depending on the specific goals and context, but it generally involves producing mushrooms for food, medicine, industry, research, education, income generation, and environmental sustainability

#### **Nutritional attributes of mushroom cultivation.**

Mushroom is considered to be a complete, health food and suitable for all age groups. The nutritional value of mushroom is affected by numerous factors such as species, stage of development and environmental condition. Mushrooms are rich in protein, dietary fiber, vitamins and minerals. In addition to nutritional value, mushroom possess unique color, taste, aroma and texture, which make them attractive for human consumption.

#### **Protein**

The protein content of four popular mushrooms, *Agaricus bisporus*, *Lentinula edodes*, *Pleurotus* spp., and *Volvariella volvacea* which are commercially cultivated, ranges from 1.75 to 3.63% of their fresh weight. On a dry weight basis, mushrooms normally contain 19 to 35% protein as compared to 7.3% in rice, 13.2% in wheat, 39.1% in soybean and 25.2% in milk.

Therefore, in amount of crude protein, mushrooms rank well above most plant products, including milk which is an animal product.

#### **Essential amino acids**

Proteins are made up from over 20 amino acids in varying amounts, out of which 9 are essential amino acids (Leucine, Isoleucine, Valine, Tryptophan, Lysine, Threonine, Phenylalanine, Methionine, and Histidine). The plant foods often lack some of the important amino acids; e.g. cereal grains have too little lysine and pulses usually lack the methionine and tryptophan. The protein of commonly cultivated mushrooms contains all 9 amino acids essential for humans. In mushroom, the most abundant essential amino acid is lysine and the lowest levels among the essential amino acids are those of tryptophan and methionine. In mushrooms, in addition to essential amino acids, the less common amino acids such as methionine sulfoxides, cystic acid, phosphoserine, citrulline, ornithine etc. are also present.

#### **Fat**

The fat content in different mushroom ranges from 1.12 to 8.30% on dry weight basis with an average content of 4%. In general, the crude fat of mushrooms has representative of all classes of lipid compounds including free fatty acids, monoglycerides, diglycerides, triglycerides, sterols, sterol esters, and phospholipids. Cholesterol level in mushroom is very low or absent and high content of ergosterol is present. At least 72% of the total fatty acids have been found to be unsaturated in mushroom. The high content of unsaturated fatty acids is mainly due to linoleic acid, which is 76% in *L. edodes*, 70% in *V. volvacea* and 69% in *A. bisporus* of the total fatty acids. Unsaturated fatty acids are essential in our diet, whereas saturated fatty acids, which are present in animal fats, may be harmful to our health.

### Vitamins

Mushrooms are a good source for several vitamins including thiamine (vit. B1), riboflavin (vit. B2), niacin, biotin and ascorbic acid (vit. C). The thiamine content in some mushrooms is 0.32 mg in *V. volvacea*, 1.1 mg in *A. bisporus*, 1.16 to 1.80 mg in *Pleurotus* spp. and 7.8 mg in *L. edodes*. The niacin content varies from species to species i.e. 54.9 mg in *L. edodes*, 47.55mg in *V. volvacea*, 55.7 mg in *A. bisporus*, and 46.19 to 64.88. mg in *Pleurotus* spp. The riboflavin content was higher in *A. bisporus* (5.0 mg), and *L. edodes* (4.9 mg) than in *V. volvacea* (1.63 mg). *L. edodes* had the highest vit. C (ascorbic acid) content (9.4 mg/100 g dry wt.), the other mushrooms were having 1.4mg in *V. volvacea*, 1.8 mg in *A. bisporus*, and 7.4mg in *Pleurotus sajor-caju*. Mushrooms are rich in ergosterol which later converts into Vit. D in our body.

### Carbohydrate & fiber

Pentoses, Hexoses, disaccharides, sugar alcohols, amino sugars and sugar acids are major constituents of mushroom carbohydrates. *Pleurotus* spp contain carbohydrates, ranging from 46.6 to 81.8% as compared to 60% in *A. bisporus* on dry wt. basis. The polysaccharides present in mushroom have ability to inhibit the growth of tumor. Fiber is considered to be an important ingredient in a balanced and healthy diet. The fiber content ranges from 7.4 to 27.6% in *Pleurotus* spp., 10.4% in *A. bisporus* and 4 to 20% in *V. volvacea*.

### Mineral

The major mineral constituents of mushrooms are potassium (K), phosphorus (P), sodium (Na), calcium (Ca) and magnesium (Mg). Major minerals, constitute about 56-70% of total ash content. Potassium is particularly abundant and accounts for nearly 45% of the total ash content. Na and Ca are present in approximately equal concentrations in all the mushrooms except for *L. edodes* in which Ca is present in large amount. The minor mineral constituents of mushrooms are copper (Cu), Zinc (Zn), iron (Fe), manganese (Mn), molybdenum (Mo) and Cadmium (Cd). The Cu content varied from 12.2 to 21.9 ppm in *Pleurotus* spp
